

# Pipeline for Our Example

Using SCALE Atmel dataset

## A Acquire training data

- 1000 traces, random known plaintexts
- Fixed known key is less ideal
- Traces are already aligned

## B Build a profile

- 1 We already identified potential Pols
- 2 Model and profiling tbd

## C Collect target traces

- 1000 traces, random known plaintexts

## D Distinguish

- 1 Template Attack
- 2 Stochastic Attack

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

### 1. From Probability to Likelihood

For each key candidate  $k$  determine its a posteriori probability *given* the observed leakage  $L$

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

### 1. From Probability to Likelihood

$$\Pr[k | L] = \frac{\Pr[L | k] \cdot \Pr[k]}{\Pr[L]}$$

$\Pr[L | k]$  is the likelihood

$\Pr[k]$  and  $\Pr[L]$  can be ignored

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

## 2. From Likelihood to Sum of Log Likelihoods

Assume each trace leaks independently, then

$$\Pr[L | k] = \prod_i \Pr[L_i | k]$$

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

## 2. From Likelihood to Sum of Log Likelihoods

Assume each trace leaks independently, then *after taking logs*

$$\log_2 \Pr[L | k] = \sum_i \log_2 \Pr[L_i | k]$$

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

## From Log Likelihood to QDA

Assume

$$L(data) \sim \hat{M}(x_i \oplus k^*) + \mathcal{N}(0, \sigma)$$

then

$$\log_2 \Pr[L_i | k] = \log_2 \mathcal{N}(L_i - \hat{M}(x_i \oplus k); 0, \sigma)$$

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

## From Log Likelihood to QDA

Assume

$$L(data) \sim \hat{M}(x_i \oplus k^*) + \mathcal{N}(0, \sigma)$$

then

$$\log_2 \Pr[L_i | k] = -\log_2 e \left( L_i - \hat{M}(x_i \oplus k) \right)^2 / 2\sigma^2 - \frac{1}{2}(1 + \log_2 \pi) - \sigma$$

# Template Attacks

## Naive Bayes

| $i$      | $x_i$    | power    |
|----------|----------|----------|
| 0        | 12       | 1.35...  |
| 1        | 123      | 4.65...  |
| $\vdots$ | $\vdots$ | $\vdots$ |
| $\vdots$ | $\vdots$ | $\vdots$ |
| 999      | 59       | 2.79...  |

 $\Rightarrow$ 

| $k_0$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

## QDA Summary

$$\text{score}(k|L) = \sum_i (L_i - \hat{M}(x_i \oplus k))^2$$

To profile:  $\hat{M}(z)$  for all 256 possible  $z$

**Warning:** Scores can no longer be interpreted as posteriors

# Template and Stochastic Attacks

## SCALE Atmel Profiling

11005

11223

## Template Attack

For all 256 possible S-box input values

- determine the sample mean
- (optional) determine the sample variance

**Problem:** 1000 traces is not enough to estimate 256 parameters

# Template and Stochastic Attacks

## SCALE Atmel Profiling

11005

11223

## Stochastic Attack

Assume the leakage model

$$M_{a,b}(k,x) = a \cdot \text{HammingWeight}(\text{Sbox}(x \oplus k)) + b$$

- estimate  $a$  and  $b$

(Warning: The right estimation is naively unweighted)

# Template Attacks

## SCALE Atmel Scores

11005

11223

## Final distinguishing scores

After incorporating 1000 target traces

**left** One candidate key *very* clearly sticks out

**right** One candidate key sticks out, but not as much

# Template Attacks

## SCALE Atmel Scores

11005

11223

### Evolution of distinguishing scores

Look at scores as a function of number of traces incorporated

**left** the true key quickly separates from the rest

**right** it takes much longer for the true key to stand out

In blue the actual keybyte

# Template Attacks

## SCALE Atmel Scores

11005

11223

### Evolution of distinguishing scores

Look at scores as a function of number of traces incorporated

**left** the true key quickly separates from the rest

**right** it takes much longer for the true key to stand out

In blue the actual keybyte

# Template Attacks

## SCALE Atmel Success Rate

11005

11223

Success Rate: Probability that best guess wins

For each  $i$  (x-axis), ran 2000 experiments:

- 1 Selected  $i$  out of 1000 traces
- 2 Check if best guess is actual keybyte

*Warning:* resampling methodology used due to available data

# Template Attacks

## SCALE Atmel Success Rate

11005

11223

### Success rate conclusion

- 1 Left performs better than right
- 2 Success rate  $2^{-2}$  for a *single* keybyte, only gives  $2^{-32}$  for the full 16-byte key.

*Note:* jaggedness likely due to low number of experiments

# Different Adversarial Scenarios

## Not-Quite-Kerckhoffs Principle

The adversary can exhaustively search the key

# Different Adversarial Scenarios

## Not-Quite-Kerckhoffs Principle

The adversary can **enumerate** the key

# Enumeration

## Enhancing Divide-and-Conquer Attacks

| $k_0$    | score    |
|----------|----------|
| 0        | 0.123... |
| 1        | 0.127... |
| $\vdots$ | $\vdots$ |
| 255      | 0.238... |

| $k_1$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

...

| $k_{15}$ | score    |
|----------|----------|
| 0        | 0.184... |
| 1        | 0.167... |
| $\vdots$ | $\vdots$ |
| 255      | 0.152... |

**Best guess** Simply output the most likely 128-bit key overall

**Key enumeration** Test keys from most likely to least likely until success

# Enumeration

## Enhancing Divide-and-Conquer Attacks

| $k_0$    | score    |
|----------|----------|
| 0        | 0.123... |
| 1        | 0.127... |
| $\vdots$ | $\vdots$ |
| 255      | 0.238... |

| $k_1$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |
| $\vdots$ | $\vdots$ |
| 255      | 0.098... |

...

| $k_{15}$ | score    |
|----------|----------|
| 0        | 0.184... |
| 1        | 0.167... |
| $\vdots$ | $\vdots$ |
| 255      | 0.152... |

Best guess obviously  $k_0 = 0, k_1 = 255, \dots, k_{15} = 255$

*But what about the next best guess?*

Question posed by Veyrat-Charvillon *et al.* (SAC'12)

# Enumeration

## Enhancing Divide-and-Conquer Attacks

| $k_0$    | score    |
|----------|----------|
| 0        | 0.123... |
| 1        | 0.127... |
| $\vdots$ | $\vdots$ |
| 255      | 0.238... |

| $k_1$    | score    |
|----------|----------|
| 0        | 0.134... |
| 1        | 0.116... |

## DPA with Enumeration

A number of cost metrics

- 1 The number of traces (profile vs.target)
- 2 The running time of the distinguisher
- 3 The number of keys to test
- 4 *The overhead (in time) to enumerate*

# Enumeration

## Enhancing Divide-and-Conquer Attacks

## Some approaches

**Naïve** Create ordered list of all  $2^{128}$  keys

**2012** Tree-like recursion algorithm

[Veyrat-Charvillon, Gérard, Renaud, Standaert / SAC]

**2015** Dynamic programming enabling **parallelization**

[Martin, O'Connell, Oswald, Stam / Asiacrypt]

# A Typical Side-Channel Attack Pipeline

## Adding Enumeration

After the **D**istinguish phase, the scores are fed to an **E**numeration phase

# A Typical Side-Channel Attack Pipeline

## Adding Enumeration

After the **D**istinguish phase, the scores are fed to an **E**numeration phase

*But how long will it take, roughly?*

Question posed by Veyrat-Charvillon *et al.* (Eurocrypt'13)

# A Typical Side-Channel Attack Pipeline

## Emulating Enumeration

After the **D**istinguishing phase,

- use *knowledge of the target key* to determine its **rank**.

Rather than running enumeration, **E**mulate it to predict its runtime

# Key Ranking

Emulating the cost of key enumeration

## Relevance: Evaluation

Many SCA are run by evaluation labs:

- The care not about actually recovering the key
- *Only* how difficult it is to do so

The target key will be known already!

## Ranking algorithms

A number of relevant metrics

- 1 The time to compute
- 2 Potential for parallelization
- 3 Quality of the returned rank when *approximating*

# Key Ranking

Emulating the cost of key enumeration

## Some algorithmic approaches

lore Adding “guessing entropies”

2013 Tree-like recursion algorithm

[Veyrat-Charvillon, Gérard, Renaud, Standaert / Eurocrypt]

2015 Dynamic programming enabling **parallelization**

[Martin, O’Connell, Oswald, Stam / Asiacrypt]

2015 Convolution of histograms

[Glowacz, Grosso, Poussier, Schüth, Standaert / FSE]

[Bernstein, Lange, van Vredendaal / eprint]

# Key Rank Distributions

Martin, Mather, Oswald, Stam / Asiacrypt'16

## The Rank Distribution

*Evaluator's task* for some keyed device:

How long will it roughly take to recover the key  
as a function of the number of traces?

# Key Rank Distributions

Martin, Mather, Oswald, Stam / Asiacrypt'16

## MMOS Setup

- AES-128 with simulated leakage
- Sbox output Hamming weight with Gaussian noise
- For SNRs  $2^x$  with  $x \in \{-7, -5, -3\}$
- Ran an unprofiled Correlation Power Attack (CPA)

# Key Rank Distributions

Martin, Mather, Oswald, Stam / Asiacrypt'16

## MMOS Lessons

- 1 Average log rank is more useful than log of average rank  
*geometric mean* versus arithmetic mean
- 2 The variance in the rank is considerable, esp. in the middle
- 3 SNR does not affect the shape of the distribution beyond scaling x-axis

# Key Rank Distributions

Martin, Mather, Oswald, Stam / Asiacrypt'16

## Challenges

- 1 Improved sensor fusion to combine subkey scores
- 2 Optimize distinguishers w.r.t. resulting key ranks
  - Model and feature selection
  - Score computation
- 3 Rank distribution against various countermeasures

# SCALE: A Resource by Dan Page

<https://github.com/danpage/scale>

## Side-Channel Attack Lab. Exercises

Provides a suite of material related to side-channel (and fault) attacks that is low-cost, accessible, relevant, coherent, and effective.

## SCALE Data Sets

- 1 Four platforms: an *Atmel atmega328p* (an AVR) plus three NXP ARM Cortex-M processors
- 2 Implementation uses an 8-bit datapath and look-up tables for the S-box and xtime operations (but code not known)
- 3  $2 \times 1000$  traces of AES-128 each (known vs. unknown key)
- 4 Traces acquired using a Picoscope 2206B, using triggers for alignment

# Power Analysis Attacks

Stefan Mangard, Elisabeth Oswald, and Thomas Popp's Classic

## Revealing the Secrets of Smart Cards

- “first comprehensive treatment of power analysis attacks and countermeasures”
- Aimed at the practitioner
- From 2007  $\Rightarrow$  no modern ideas and theory

# CHES

An IACR Conference

## Cryptographic Hardware and Embedded Systems

Established in 1999

- Efficient implementations
- How to mount implementation attacks
- How to protect against them
- New designs that allow efficient yet secure implementations
